Software Development Life Cycle (SDLC)

Moving from Exploratory programming to Software Engineering

- The early programmers used an exploratory (also called build and fix) style.
 - In the build and fix (exploratory) style, normally a 'dirty' program is quickly developed.
 - The different imperfections that are subsequently noticed are fixed.

What is Wrong with the Exploratory Style?

Lan successfully be used for very small programs only.

What is Wrong with the Exploratory Style?

- Besides the exponential growth of effort, cost, and time with problem size:
 - Exploratory style usually results in unmaintainable code.
 - It becomes very difficult to use the exploratory style in a team development environment.
- Why does the effort required to develop a product grow exponentially with product size?
 - Why does the approach completely break down when the product size becomes large?

Programs versus Software Products

Usually small in size Large Large number of users Author himself is sole user Team of developers Single developer Well-designed interface Lacks proper user interface Well documented & usermanual-prepared-Lacks proper documentation Systematic development Ad hoc development.

Types of software

Custom

For a specific customer

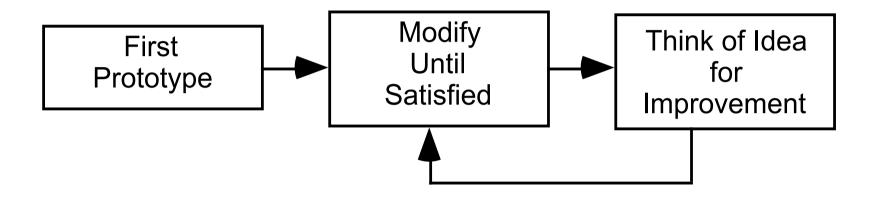

Generic

▶ COTS (Commercial Off The Shelf)

Embedded

Build into Hardware

The opportunistic approach

- OK for small, informal projects
- Inappropriate for professional environments/complex software where on-time delivery and high quality are expected

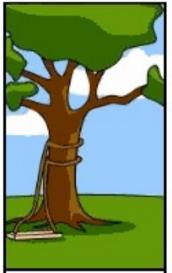

How the customer explained it

How the Project Leader understood it

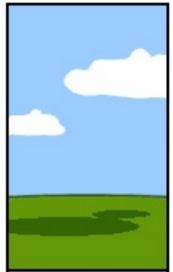

How the Analyst designed it

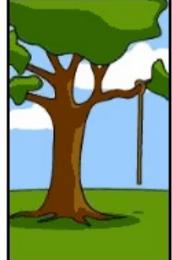

How the Programmer wrote it

How the Business Consultant described it

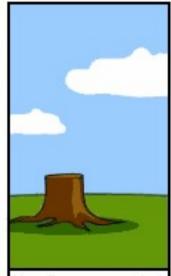

How the project was documented

What operations installed

How the customer was billed

How it was supported

What the customer really needed

Why Life cycle model?

- A software project will never succeed if activities are not coordinated:
 - one engineer starts writing code,
 - another concentrates on writing the test document first,
 - > yet another engineer first defines the file structure
 - ▶ another defines the I/O for his portion first
- Adherence can lead to accurate status reports
- Otherwise, it becomes very difficult to track the progress of the project
 - the project manager would have to depend on the guesses of the team members.

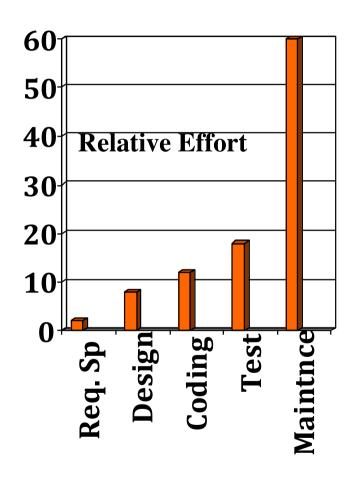

Software Development Life Cycle (SDLC)

- Typical software life cycle or software process consists of following phases:
 - Feasibility study (involves business case)
 - ▶ Requirements analysis and specification,
 - Design
 - Coding
 - Testing
 - Maintenance

Relative effort for Phases

- Phases between feasibility study and testing
 - known as development phases.

- Among all life cycle phases
 - maintenance phase consumes maximum effort.

Requirements Engineering

- Aim of this phase:
 - understand the <u>exact requirements</u> of the customer,
 - document them properly.

- Consists of two distinct activities:
 - requirements gathering and analysis
 - requirements specification.

Requirements Gathering

- Gathering relevant data:
 - usually collected from the end-users through interviews and discussions.
 - For example, for a business accounting software:
 - Interview all the accountants of the organization to find out their requirements.

Goals of Requirements Analysis

- Collect all related data from the customer:
 - analyze the collected data to clearly understand what the customer wants,
 - ensure correctness, consistency and unambiguity.

Requirements Analysis (CONT.)

- The data you initially collect from the users:
 - would usually contain several contradictions and ambiguities:
 - each user typically has only a partial and incomplete view of the system.
- Ambiguities and contradictions:
 - must be identified
 - resolved by discussions with the customers.
- Next, requirements are organized:
 - into a Software Requirements Specification (SRS) document

Design

- Design phase transforms requirements specification:
 - into a form suitable for implementation in some programming language.

Design

High-level design:

- decompose the system into *modules*,
- represent invocation relationships among the modules.

Detailed design:

- different modules designed in greater detail:
 - data structures and algorithms for each module are designed.

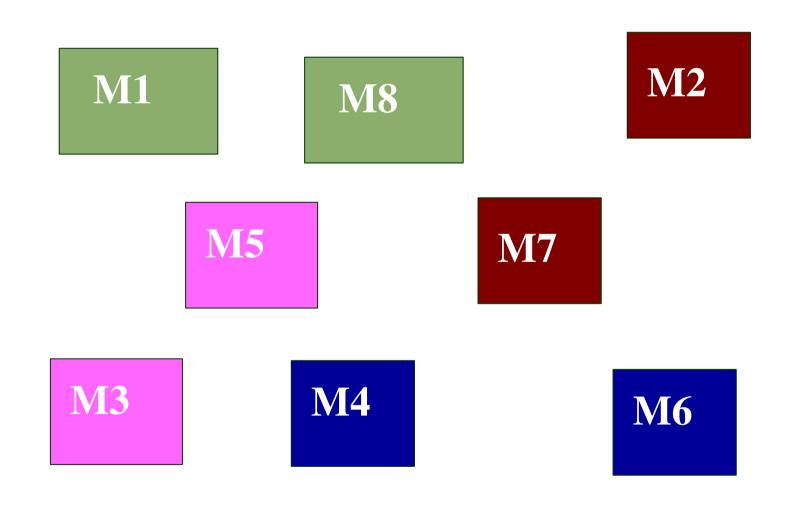

Implementation

- During the implementation phase:
 - each module of the design is coded,
 - each module is unit tested
 - tested independently as a stand alone unit, and debugged
- The purpose of unit testing:
 - test if individual modules work correctly.
- ▶ The end product of implementation phase:
 - a set of program modules that have been tested individually

Integration and System Testing

- Different modules are integrated in a planned manner:
 - modules are almost never integrated in one shot.
 - Normally integration is carried out through a number of steps.
- During each integration step,
 - by the partially integrated system is tested.

Integration and System Testing

Maintenenace

- Maintenance of any software product:
 - requires much more effort than the effort to develop the product itself.
 - development effort to maintenance effort is typically 40:60.

Maintenance (CONT.)

Preventive maintenance

Making appropriate changes to prevent the occurrence of errors

Corrective maintenance

Correct errors which were not discovered during the product development phases

Perfective maintenance

- Improve implementation of the system
- enhance functionalities of the system

Adaptive maintenance

Port software to a new environment

Summary

- A software life cycle model (or process model):
 - a descriptive and diagrammatic model of software life cycle
 - identifies all the activities required for product development,
 - establishes a precedence ordering among the different activities
 - divides life cycle into phases.
- A fundamental necessity while developing any large software product:
 - Adoption of a software development life cycle model (software process model).
